FOR: NEW SUPERCONDUCTIVE COMPOUNDS HAVING HIGH TRANSITION TEMPERATURE,
AND METHODS FOR THEIR USE AND PREPARATION

DECLARATION OF J. GEORG BEDNORZ AND K.A. MUELLER
WITH RESPECT TO HIGH T_c SUPERCONDUCTIVITY

Commissioner of Patents and Trademarks
Washington, D. C. 20231

Sir:

We, J. Georg Bednorz and K.A. Mueller, hereinafter say and declare the following:

1. We are the inventors of the contribution described and claimed in the subject U.S. patent application. This application describes our earlier discovery of high temperature superconductivity in ceramic copper oxide materials. In particular, one of the earlier systems in which we worked was comprised of Ba-La-Cu-oxides which exhibited superconducting onset temperatures in the mid ~~low~~ ^W _{thirty} K range. JG

2. We conducted extensive research on these materials to establish their superconductivity in our laboratory in Zurich, Switzerland. This work traced back to early 1986 and was described in a publication by us that appeared in Z. Phys. B - Condensed Matter 64, 189-193 (1986). This article describes, among other items, resistivity versus temperature measurements that we made on samples of this material to show its superconductive behavior. We subsequently submitted for publication and had published additional articles describing these high T_c oxide superconductors.

3. On approximately October 16, 1986, we gave Praveen Chaudhari (Vice-President, Science at the Yorktown Research Laboratory of IBM Corporation) six samples of the high temperature superconductive ceramic oxide material that we had described in our aforementioned Z. Physik B. publication. Praveen Chaudhari brought these samples back to the U.S. when he returned after

visiting with us on or about October 16, 1986. These samples were given to him so that experimentation and measurement could be performed on the samples in the United States. We knew the individuals (Richard Greene and Chang C. Tsuei) who would be involved in the measurements in the United States and discussed the measurements with these individuals in approximately the third week of October, 1986. We maintained telephone and computer communications with these individuals from that time continually through the remainder of 1986 and into 1987.

4. It was decided by us that Richard Greene would do specific heat measurements on these samples while magnetic measurements would be done by us in our Zurich laboratory. Greene worked for Chang Tsuei and discussed with him the nature of the experiments and development activities to be performed at the aforementioned Yorktown lab. We provided guidance to Richard Greene and Chang Tsuei by describing the nature of these superconducting samples and the types of properties that we had measured relative to these samples. One of us (K.A. Mueller) also discussed confirmation of our resistivity versus temperature measurements with said Chang Tsuei in a telephone conversation in October, 1986.

5. The early work conducted by the individuals in the Yorktown laboratory on our superconducting samples occurred with the supervision and guidance that we furnished to these Yorktown scientists. Additionally, we provided a preprint to Richard Greene of an article that we subsequently published in *Europhysics Letters* 3, (3), pp. 379-385 (1987). This article was given to Greene in October, 1986 and described magnetic measurements on these superconducting samples.

6. We were aware of the work being conducted on our samples at the Yorktown lab and were in contact with the individuals there, and particularly Richard Greene, who reported to Chang Tsuei. Since the specific heat measurements generally take longer, we had considerable interactions with Rick Green over a period of time from about October 22, 1986 through December, 1986, concerning his specific heat measurements. We also were made aware of Chang Tsuei's measurements of resistivity versus temperature of the Ba-La-Cu-oxide samples, which confirmed our earlier resistivity versus temperature measurements.

7. We further declare that all statements made hereinabove based on our own knowledge are true and that all statements made on information and belief are believed to be true. We further declare

that these statements are made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of our Patent Application or any patent issuing thereon.

DECLARATION OF ALEXIS P. MALOZEMOFF
WITH RESPECT TO HIGH T_c SUPERCONDUCTIVITY

Commissioner of Patents and Trademarks
Washington, D.C. 20231

Sir:

I, Alexis P. Malozemoff, hereby declare and say that:

1. I have a PhD from Stanford University and was a Senior Manager in the Physical Sciences Department at the Thomas J. Watson Research Center of IBM Corporation at Yorktown, N.Y. in the fall of 1986. At that time, Chang C. Tsuei reported to me while Richard Greene and Sung Il Park reported to Chang Tsuei. I had general responsibility for a research program in superconductivity and amorphous materials.

2. In approximately September - October 1986, I was made aware of the pioneering work in superconductivity done by Bednorz and Mueller in Zurich. I had seen an activity report prepared by the Zurich Research lab of IBM Corporation, which detailed that work and the measurements that Bednorz and Mueller had made on Ba-La-Cu-O ceramic superconductors. In response, I discussed specific heat measurements that could be made on these superconducting materials to complement the work being done at Zurich by Bednorz and Mueller. My discussion was with Richard Greene whom I encouraged to be involved in this technical activity.

3. On or about November 15, 1986, Richard Greene and I traveled to Baltimore for a Magnetism conference. During our travel to Baltimore, we discussed Greene's ongoing experiments on high T_c superconducting samples

Y0987-074

which he said had been received from Bednorz and Mueller. Specifically, we discussed Greene's preliminary data on specific heat measurements. Richard Greene reported to me that the diamagnetic signal was present but very small. I encouraged him to continue with his measurements with the anticipation that he might be able to present a paper at the Materials Research Society meeting that was scheduled for December, 1986.

4. I recall Chang Tsuei telling me his measurements of resistivity versus temperature on the superconducting samples of Ba-La-Cu-Oxides which had been obtained from Zurich. These measurements were done at the aforementioned Research Center and Tsuei reported that his measurements confirmed earlier measurements of Bednorz and Mueller and were consistent with the results published by Bednorz and Mueller in Z. Phys. B-Condensed Matter 64, pp. 189-193 (1986). My recollection of the exact date Chang Tsuei told me of his resistivity versus temperature measurements is not clear. However, I do know that he told me in either November or December of 1986. To the best of my recollection, Tsuei's discussion with me was shortly after the Materials Research Society meeting in Boston the first week of December, 1986.

5. I do have a strong recollection of the work of Richard Greene on the specific heat measurements of these samples and of his measurements of resistivity versus temperature in the presence of a magnetic field. Greene's work at the Research Center started soon after he received the superconducting samples in October, 1986 and continued on a daily basis throughout the remainder of 1986 and into 1987. He discussed with me and showed me data concerning these measurements, which indicated to me that a portion of the samples was superconducting. During this time he told me that he also communicated regularly with Bednorz and Mueller in Zurich to inform them of his work and to coordinate his efforts with those of Bednorz and Mueller. He said that he received technical guidance and support from Bednorz and Mueller and worked in complete collaboration with these individuals.

6. I further declare that all statements made hereinabove are of my own knowledge and are true and that all statements made on information and belief are believed by me to be true. Further, I declare that these statements were made in the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under

Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of a Patent Application or any patent issuing thereon.

AND METHODS FOR THEIR USE AND PREPARATION

DECLARATION OF CHENG-CHUNG JOHN CHI
WITH RESPECT TO HIGH T_C SUPERCONDUCTIVITY

Commissioner of Patents and Trademarks
Washington, D. C. 20231

Sir:

I, Cheng-Chung John Chi, hereby declare and say the following:

1. I have a PhD in Physics which I received from the University of Pennsylvania in 1976. After graduation, I did Post-doctoral work at the University of California, Berkeley and then joined the Research Division of IBM Corporation in 1979. I am presently a research staff member on the technical staff of the Director of Research at the Thomas J. Watson Research Center of IBM Corporation located at Yorktown, New York.

2. At a time prior to approximately the middle of November, 1986, Chang C. Tsuei told me of measurements he made on samples of high T_C superconducting material which he said were received from Georg Bednorz and K. A. Mueller, two physicists working for IBM Corporation in Zurich, Switzerland. These samples of superconducting material were La-Ba-Cu-O crystalline materials of the type described by Bednorz and Mueller in Z. Phys. B-Condensed Matter 64, pp. 189-193 (1986). Chang Tsuei said that he had measured resistivity versus temperature of these samples.

3. In the time frame mentioned hereinabove, Chang Tsuei showed me plots of resistivity versus temperature for the measurements he had made on these superconducting samples. I recall him telling me that the superconducting transition was "not really sharp", which is to

YO987-074

be expected for samples prepared during the infancy of a technology development. I recognized that these plots were evidence of superconductivity with high T_c , even if the transition were not very sharp at that time. Based on Tsuei's statements to me, I believe that these resistivity versus temperature plots were shown to me within a day or two of the time Tsuei made these measurements in his laboratory.

4. All acts described by me in this declaration occurred in the United States.

5. I further declare that all statements made hereinabove are of my own knowledge and are true and that all statements made on information and belief are believed by me to be true. Further, I declare that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of a Patent Application or any patent issuing thereon.

AND METHODS FOR THEIR USE AND PREPARATION

DECLARATION OF SUNG IL PARK
WITH RESPECT TO HIGH T_c SUPERCONDUCTIVITY

Commissioner of Patents and Trademarks
Washington, D.C. 20231

Sir:

I, Sung Il Park, hereby declare and say that:

1. I received a PhD in Applied Physics from Stanford University in October, 1986. I joined the Thomas J. Watson Research Center of IBM Corporation in Yorktown, N.Y. on approximately October 20, 1986, and began work as a Post-doctoral employee. My initial assignment was in the areas of Thin Film Interfaces and high T_c superconductivity. Almost from the beginning of my employment by IBM Corporation I worked exclusively on high T_c superconductivity and reported to Chang C. Tsuei. I am presently working in the same capacity for Chang C. Tsuei, one hundred percent of my time being spent on high T_c superconductivity.

2. I was told by Chang C. Tsuei that superconducting samples had been received by Richard Greene, the samples having been brought from IBM Corporation's Research Lab in Zurich, Switzerland. These were said to be Ba-La-Cu-Oxides that had been fabricated by Georg Bednorz and Alex Mueller in Zurich, Switzerland and transported to the U.S. by Praveen Chaudhari. Soon after I began working for Chang C. Tsuei, he asked me to prepare two of these samples for measurements of resistivity versus temperature. To do so, I and Greene cut pieces from these samples to be used for the measurements. I then pressed indium dots into these cut samples to provide electrical contacts. I attached copper wires

YO987-074

to the indium dots in order to allow connections to a current source and to voltage-measuring equipment. The individual copper wires were given number designations to allow them to be properly attached to the equipment used for the current and voltage measurements. This numbering system is represented by the two figures appearing in Chang C. Tsuei's laboratory notebook, a true copy of two pages of which are attached hereto and labeled Exhibit A.

3. In order to determine resistivity versus temperature, measurements were made of the current flowing through the Ba-La-Cu-Oxide sample while the voltage across two of the copper leads was measured. Both positive and negative polarity currents were used in order to avoid thermal effects that sometimes occur when making DC measurements. The superconducting sample was located on the end of a long probe and placed in a dewar containing liquid helium. The temperature was varied by using a heater placed near the sample. Data of current and voltage were taken from 4.2K to 50K. A germanium thermometer near the sample was used to measure the sample temperature. Since resistance is proportional to voltage, the voltage and current measurements allowed the resistance (and therefore the resistivity for a sample of known dimensions) to be measured as a function of temperature. I worked with Chang C. Tsuei to take these measurements and used a xy recorder to provide graphical plots of resistivity versus temperature for the temperature range 50K-4.2K for at least two of these Ba-La-Cu-Oxide samples.

4. The preparation and measurement of the aforementioned superconducting samples occurred at a date prior to November 15, 1986, and to the best of my recollection occurred on or about November 9, 1986, the date when a helium dewar was pumped down preparatory to taking the actual measurements. I believe that while I was assisting Chang C. Tsuei and working under his direction, Bradford Orr observed our data and graphical plots, and we told him the nature of the superconducting samples and the types of measurements that we were making.

5. My recollection of the dates when the preparation and measurement of these samples occurred is vivid to me. My first week of employment under Chang C. Tsuei was spent looking for an apartment and, upon beginning laboratory work the following week (about October 28, 1986), I was instructed by Chang C. Tsuei to immediately measure the

aforementioned samples. I cut pieces from these samples using a fine wire cutter following the direction of Richard Greene. This was done on or about October 28, 1986. After this I contacted the samples with indium as described above. This technique was very familiar to me as I had used indium contacts many times at Stanford University.

6. Both Chang C. Tsuei and I were enthused about our measurement results, as the data showed a superconducting onset temperature of about 35K followed by a drop to zero DC resistivity. We noted that the transition to zero resistivity was fairly wide, which we expected to be the case for samples that may have been unperfected and not of a single phase. In fact, the question of whether multiple phases were present in the material was something that was noted by Tsuei in the aforementioned laboratory notebook, identified as Exhibit A, attached hereto.

7. At this time, I have been unable to locate the actual data and graphical plots of resistivity versus temperature described hereinabove. I believe that this data may have been misplaced or inadvertently thrown out during an extensive cleaning of the laboratory. However, my memory of the events preparing the samples for measurements, performing the measurements and recording the data, and the results indicated by that data, are very clear in my mind.

8. All of the acts described in paragraphs 1 - 7 above occurred in the United States.

9. I further declare that all statements made hereinabove are of my own knowledge and are true and that all statements made on information and belief are believed by me to be true. Further, I declare that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of a Patent Application or any patent issuing thereon.

FOR: NEW SUPERCONDUCTIVE COMPOUNDS HAVING HIGH TRANSITION TEMPERATURE,
AND METHODS FOR THEIR USE AND PREPARATION

DECLARATION OF CHANG C. TSUEI
WITH RESPECT TO HIGH T_c SUPERCONDUCTIVITY

Commissioner of Patents and Trademarks
Washington, D.C. 20231

Sir:

I, Chang C. Tsuei, hereby declare and say that:

1. I have a PhD in Material Science from California Institute of Technology, and worked approximately eleven years as a student and faculty member at Cal. Tech. During this time, my research was primarily on amorphous materials and superconducting materials. I joined the Thomas J. Watson Research Center of IBM Corporation in Yorktown, N.Y. in 1973 and continued my work on amorphous materials. For several years, I have been the Manager of a group in the Physical Sciences Department studying amorphous superconductivity and superconductivity of new High T_c superconducting ceramic materials.

2. On approximately September 13, 1986, I returned from a sabbatical at the K. Onnes Laboratory in Holland. Upon my return, I saw a copy of an IBM activity report for May - June, 1986, in which the "novel research" of J.G. Bednorz and K.A. Mueller was described. These individuals were working in the Zurich, Switzerland research laboratory of IBM Corporation, and had observed a steep decrease of resistivity in sintered samples of Ba-La-Cu-oxides. A true copy of this activity report is attached hereto and labeled Exhibit A. On page 2 of the activity report the resistivity versus temperature plot is shown in Figure 1

wherein the onset temperature for superconductivity is in the 35K range. The data and measurements discussed in the activity report were later published by Bednorz and Mueller in Z. Phys. B-Condensed Matter, 64, pp. 189 - 193 (1986), a true copy of which is attached and labeled Exhibit B. Based on my previous experience in superconductivity, I was very interested in the work of Bednorz and Mueller and discussed this work with my colleague, Richard Greene (who reported to me). I told Greene to review this activity report and to start a project on high T_c superconductors of the type described by Bednorz and Mueller. This project was started by Richard Greene and others in the group that reported to me, almost immediately.

3. I called Alex Mueller in Switzerland via telephone to request samples of his superconducting material, as well as to discuss the technical area with him. I also sent computer messages to Mueller, but could not contact him. After this, early in October, 1986, I obtained a copy of the aforementioned Z. Phys. B article by Bednorz and Mueller.

4. I knew that on approximately October 17, 1986, Praveen Chaudhari was in Zurich, Switzerland. I was told that he was given samples of the Bednorz and Mueller superconducting copper oxides to bring to the U.S. for collaborative work in the United States. I was also told that these superconducting samples were delivered to Richard Greene on or about October 22, 1986. Shortly after these superconducting samples were received, I began work to confirm the existence of high temperature superconductivity in these materials and instructed Sung Il Park to assist me. To do so, small pieces of these samples were cut by Park and Greene and were prepared with indium contact dots to which copper wires were attached. These copper wires were attached to a source of electrical current and to voltage-measuring equipment to determine the existence of the superconducting state. As the temperature of the sample was lowered, resistivity versus temperature plots were then made using standard laboratory techniques. The preparation of these samples for measurement was done by Sung Il Park, who reported to me and who was directed by me to do so.

5. A true copy of the cover sheet and a page of my laboratory notebook is attached hereto and labeled Exhibit C. On the second page of

this exhibit, two diagrams illustrate the samples and show the location of the indium contact dots on the superconducting samples and the numbering given to the copper wires attached to these dots. This numbering enabled us to properly connect these wires to a current source and to voltage-measuring equipment. All entries on this notebook page were made by me. The samples are generally designated by their composition, the term "BLCO" standing for Ba-La-Cu-Oxide materials. The designation "BLCO 21 -- II," etc. in the box in the right hand corner of this page and the designation "BLCO 2 I" in the circle in the middle of the page were the designations on the sample boxes in which the samples were located. I copied these designations directly into my notebook. On the bottom right hand corner of this exhibit, the words "dewar pumped 3×10^{-5} Torr 11/9/86" is indicated. I made this notation on November 9, 1986 indicating that the dewar was being pumped down in order to enable the resistivity versus temperature measurements to be made. Because this dewar leaked, the actual measurements had to be made within several hours of the pump-down.

6. The individual superconducting samples were attached to a long probe and slowly lowered into the liquid helium dewar while a current was passed through the sample and the voltage across two of the terminals measured. Sung Il Park assisted me. These measurements were recorded directly on an xy recorder which plotted resistivity versus temperature for these superconducting samples. These plots indicated an onset of superconductivity at about approximately 35K, and confirmed the results of Bednorz and Mueller in Switzerland. As an example, referring to the sample BLCO 2 having connecting wires 20, 21, 22 and 8, electrical current was applied between wires 20 and 8, while voltage measurements were made across the sample using contact terminals 21 and 22. Since the voltage is a function of the resistance of the material, by making the voltage measurements at constant currents, resistivity versus temperature plots can be developed. These resistivity versus temperature plots appear to be missing at this time. I believe that they may have been inadvertently thrown away when the laboratory was subsequently extensively cleaned.

7. During my measurement of the superconducting samples described hereinabove, Bradford G. Orr, who was a Post-doctoral employee

at the Research Center, came into my lab and observed these measurements, as did Albert M. Torressen. These measurements confirmed the high temperature superconductivity of these materials and I was enthusiastic about the results. I expressed my enthusiasm to Richard Greene, who was anxious to do specific heat measurements on these samples. Subsequent to my confirmation of their resistivity versus temperature measurements, I contacted Mueller in Zurich to inform him of my successful resistivity versus temperature measurements. In addition, I told several people about my laboratory measurements, including Arthur Williams, Alex Malozemoff, Paul Horn, and Praveen Chaudhari, all of whom work in the Thomas J. Watson Research Center.

8. From the time we received the superconducting samples in October, 1986 to the present, I, Richard Greene and Sung Il Park have worked on a daily basis to further explore and develop this technology. In particular, I observed Greene working on a daily basis to conduct specific heat measurements during November and December, 1986.

9. All acts described hereinabove relating to sample preparation, measurement and discussions of these measurements occurred in the United States.

10. I further declare that all statements made hereinabove are of my own knowledge and are true and that all statements made on information and belief are believed by me to be true. Further, I declare that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of a Patent Application or any patent issuing thereon.

Novel Research

Possible High-T_c Superconductivity in the Ba-La-Cu-O System

J.G. Bednorz and K.A. Müller (Project 4196)

We observed a steep decrease of resistivity in sintered Ba-La-Cu-oxide samples, with the highest temperature of the onset in the 35 K range (Fig. 1).

The Ba-La-Cu-O system exhibits a number of oxygen deficient phases with perovskite-like layer-type structures. These are characterized by mixed-valent copper ions (Cu^{2+} and Cu^{3+}) and itinerant electronic states. In addition one expects polaron formation induced by the strong Jahn-Teller effect of Cu^{2+} in an octahedral oxygen environment. Thus our Ba-La-Cu-O system was anticipated to have considerable electron-phonon coupling and metallic conductivity.

Compounds with the composition $\text{Ba}(x)\text{La}(5-x)\text{Cu}(5)\text{O}(5[3-y])$ have been prepared in polycrystalline form. Samples with $x < 0.2$ and $y > 0$, annealed below 900°C under reducing conditions, consist of three phases, one of them a perovskite-like mixed-valent copper compound with K_2NiF_4 type structure. Upon cooling, the samples show a linear decrease in resistivity, then an approximately logarithmic increase, interpreted as a beginning of localization. Finally a steep decrease by up to three orders of magnitude occurs, reminiscent of the onset of percolative superconductivity. The highest onset temperature is observed in the 35 K range. It is markedly reduced by high current densities (Fig. 1). The slow sensitivity decay towards low temperatures might possibly result from 2D superconducting fluctuations of perovskite layers of one of the phases present.

Possible High T_c Superconductivity in the Ba-La-Cu-O System

J.G. Bednorz and K.A. Müller

IBM Zürich Research Laboratory, Rüschlikon, Switzerland

Received April 17, 1986

Metallic, oxygen-deficient compounds in the Ba-La-Cu-O system, with the composition $\text{Ba}_x\text{La}_{5-x}\text{Cu}_5\text{O}_{5(3-y)}$ have been prepared in polycrystalline form. Samples with $x=1$ and 0.75 , $y>0$, annealed below 900°C under reducing conditions, consist of three phases, one of them a perovskite-like mixed-valent copper compound. Upon cooling, the samples show a linear decrease in resistivity, then an approximately logarithmic increase, interpreted as a beginning of localization. Finally an abrupt decrease by up to three orders of magnitude occurs, reminiscent of the onset of percolative superconductivity. The highest onset temperature is observed in the 30 K range. It is markedly reduced by high current densities. Thus, it results partially from the percolative nature, but possibly also from 2D superconducting fluctuations of double perovskite layers of one of the phases present.

1. Introduction

"At the extreme forefront of research in superconductivity is the empirical search for new materials" [1]. Transition-metal alloy compounds of $A15$ (Nb_3Sn) and $B1$ (NbN) structure have so far shown the highest superconducting transition temperatures. Among many $A15$ compounds, careful optimization of Nb-Ge thin films near the stoichiometric composition of Nb_3Ge by Gavalev et al. and Testardi et al. a decade ago allowed them to reach the highest $T_c=23.3$ K reported until now [2, 3]. The heavy Fermion systems with low Fermi energy, newly discovered, are not expected to reach very high T_c 's [4].

Only a small number of oxides is known to exhibit superconductivity. High-temperature superconductivity in the Li-Ti-O system with onsets as high as 13.7 K was reported by Johnston et al. [5]. Their x-ray analysis revealed the presence of three different crystallographic phases, one of them, with a spinel structure, showing the high T_c [5]. Other oxides like perovskites exhibit superconductivity despite their small carrier concentrations, n . In Nb-doped SrTiO_3 , with $n=2 \times 10^{20} \text{ cm}^{-3}$, the plasma edge is below the highest optical phonon, which is therefore unshielded

[6]. This large electron-phonon coupling allows a T_c of 0.7 K [7] with Cooper pairing. The occurrence of high electron-phonon coupling in another metallic oxide, also a perovskite, became evident with the discovery of superconductivity in the mixed-valent compound $\text{BaPb}_{1-x}\text{Bi}_x\text{O}_3$ by Sleight et al., also a decade ago [8]. The highest T_c in homogeneous oxygen-deficient mixed crystals is 13 K with a comparatively low concentration of carriers $n=2-4 \times 10^{21} \text{ cm}^{-3}$ [9]. Flat electronic bands and a strong breathing mode with a phonon feature near 100 cm^{-1} , whose intensity is proportional to T_c , exist [10]. This last example indicates that within the BCS mechanism, one may find still higher T_c 's in perovskite-type or related metallic oxides, if the electron-phonon interactions and the carrier densities at the Fermi level can be enhanced further.

Strong electron-phonon interactions in oxides can occur owing to polaron formation as well as in mixed-valent systems. A superconductivity (metallic) to bipolaronic (insulator) transition phase diagram was proposed theoretically by Chakraverty [11]. A mechanism for polaron formation is the Jahn-Teller effect, as studied by Höck et al. [12]. Isolated Fe^{4+} , Ni^{3+} and Cu^{2+} in octahedral oxygen environment

show strong Jahn-Teller (J.T.) effects [13]. While SrFe(VI)O_3 is distorted perovskite insulator, LaNi(II)O_3 is a J.T. undistorted metal in which the transfer energy b_x of the J.T. e_g electrons is sufficiently large [14] to quench the J.T. distortion. In analogy to Chakraverty's phase diagram, a J.T.-type polaron formation may therefore be expected at the borderline of the metal-insulator transition in mixed perovskites, a subject on which we have recently carried out a series of investigations [15]. Here, we report on the synthesis and electrical measurements of compounds within the Ba-La-Cu-O system. This system exhibits a number of oxygen-deficient phases with mixed-valent copper constituents [16], i.e., with itinerant electronic states between the non-J.T. Cu^{3+} and the J.T. Cu^{2+} ions, and thus was expected to have considerable electron-phonon coupling and metallic conductivity.

II. Experimental

1. Sample Preparation and Characterization

Samples were prepared by a coprecipitation method from aqueous solutions [17] of Ba-, La- and Cu-nitrate (SPECPURE JMC) in their appropriate ratios. When added to an aqueous solution of oxalic acid as the precipitant, an intimate mixture of the corresponding oxalates was formed. The decomposition of the precipitate and the solid-state reaction were performed by heating at 900 °C for 5 h. The product was pressed into pellets at 4 kbar, and reheated to 900 °C for sintering.

2. X-Ray Analysis

X-ray powder diffractograms (System D 500 SIE-MENS) revealed three individual crystallographic phases. Within a range of 10° to 80° (2 θ), 17 lines could be identified to correspond to a layer-type perovskite-like phase, related to the K_2NiF_4 structure ($a=3.79$ Å and $c=13.21$ Å) [16]. The second phase is most probably a cubic one, whose presence depends on the Ba concentration, as the line intensity decreases for smaller $x(\text{Ba})$. The amount of the third phase (volume fraction > 30% from the x-ray intensities) seems to be independent of the starting composition, and shows thermal stability up to 1,000 °C. For higher temperatures, this phase disappears progressively, giving rise to the formation of an oxygen-deficient perovskite ($\text{La}_3\text{Ba}_x\text{Cu}_6\text{O}_{14}$) as described by Michel and Raveau [16].

Fig. 1. Temperature dependence of resistivity in $\text{Ba}_x\text{La}_{3-x}\text{Cu}_5\text{O}_{8-x}$ for samples with $x(\text{Ba})=1$ (upper curves, left scale) and $x(\text{Ba})=0.75$ (lower curve, right scale). The first two cases also show the influence of current density

3. Conductivity Measurements

The dc conductivity was measured by the four-point method. Rectangular-shaped samples, cut from the sintered pellets, were provided with gold electrodes and contacted by In wires. Our measurements between 300 and 4.2 K were performed in a continuous-flow cryostat (Leybold-Heraeus) incorporated in a computer-controlled (IBM-PC) fully-automatic system for temperature variation, data acquisition and processing.

For samples with $x(\text{Ba}) \leq 1.0$, the conductivity measurements, involving typical current densities of 0.5 A/cm², generally exhibit a high-temperature metallic behaviour with an increase in resistivity at low temperatures (Fig. 1). At still lower temperatures, a sharp drop in resistivity (>90%) occurs, which for higher currents becomes partially suppressed (Fig. 1; upper curves, left scale). This characteristic drop has been studied as a function of annealing conditions, i.e., temperature and O_2 partial pressure (Fig. 2). For samples annealed in air, the transition from itinerant to localized behaviour, as indicated by the minimum in resistivity in the 80 K range, is not very pronounced. Annealing in a slightly reducing atmosphere, however, leads to an increase in resistivity and a more pronounced localization effect. At the same time, the onset of the resistivity drop is shifted

Fig. 2. Low-temperature resistivity of samples with $x(\text{Ba})=1.0$, annealed at O_2 partial pressure of 0.2 bar (curve ①) and 0.2×10^{-4} bar (curves ② to ⑦)

towards the 30 K region. Curves ④ and ⑤, recorded for samples treated at 900 °C, show the occurrence of a shoulder at still lower temperature, more pronounced in curve ⑤. At annealing temperatures of 1,040 °C, the highly conducting phase has almost vanished. As mentioned in the Introduction, the mixed-valent state of copper is of importance for electron-phonon coupling. Therefore, the concentration of electrons was varied by the Ba/La ratio. A typical curve for a sample with a lower Ba concentration of 0.75 is shown in Fig. 1 (right scale). Its resistivity decreases by at least three orders of magnitude, giving evidence for the bulk being superconducting below 13 K with an onset around 35 K, as shown in Fig. 3, on an expanded temperature scale. The latter figure also shows the influence of the current density, typical for granular compounds.

III. Discussion

The resistivity behaviour of our samples. Fig. 1, is qualitatively very similar to the one reported in the Li-Ti-O system, and in superconducting

Fig. 3. Low-temperature resistivity of a sample with $x(\text{Ba})=0.75$, recorded for different current densities

$\text{BaPb}_{1-x}\text{Bi}_x\text{O}_3$ polycrystalline thin films [5, 18]. Upon cooling from room temperature, the latter exhibit a nearly linear metallic decrease of $\rho(T)$, then a logarithmic type of increase, before undergoing the transition to superconductivity. One could, of course, speculate that in our samples a metal-to-metal structural phase transition occurs in one of the phases. The shift in the drop in $\rho(T)$ with increasing current density (Fig. 3), however, would be hard to explain with such an assumption, while it supports our interpretation that we observe the onset of superconductivity of percolative nature, as discussed below. In $\text{BaPb}_{1-x}\text{Bi}_x\text{O}_3$, the onset of superconductivity has been taken at the resistivity peak [18]. This assumption appears to be valid in percolative systems, i.e., in the thin films [18] consisting of polycrystals with grain boundaries, or when different crystalline phases with interpenetrating grains are present, as found in the Li-Ti-O [5] or in our Ba-La-Cu-O system. The onset can also be due to fluctuations in the superconducting wave functions. We assume one of the Ba-La-Cu-O phases exhibits this behaviour. Therefore, under the above premises, the peak in $\rho(T)$ at 35 K, observed for an $x(\text{Ba})=0.75$ (Fig. 1), has

to be identified as the start to superconductive cooperative phenomena in the isolated grains. It should be noted that in granular Al, Cooper pairs in coupled grains have been shown to exist already at a point where $\rho(T)$ upon cooling has decreased by only 20% of its highest value. This has been proven qualitatively [19] and more recently also quantitatively [20] by the negative frequency shift occurring in a microwave cavity. In 100 Å films, a shoulder in the frequency shift owing to 2D fluctuations was observed above the T_c of the grains. In our Ba-La-Cu-O system, a series of layer-like phases with considerable variety in compositions are known to exist [16, 21], and therefore 2D correlations can be present.

The granularity of our system can be justified from the structural information, and more quantitatively from the normal conductivity behaviour. From the former, we know that more than one phase is present and the question arises how large are the grains. This can be inferred from the logarithmic fingerprint in resistivity. Such logarithmic increases are usually associated with beginning of localization. A most recent example is the Anderson transition in granular Sn films [22]. Common for the granular Sn and our samples is also the resistivity at 300 K, lying in the range of 0.06 to 0.02 Ωcm, which is near the microscopic critical resistivity of $\rho_c = 10 L_0 h/e^2$ for localization. From the latter formula, an interatomic distance L_0 in the range of 100 Å is computed, thus a size of superconducting grains of this order of magnitude must be present. Upon cooling below T_c , Josephson junctions between the grains phase-lock progressively [23] and the bulk resistivity gradually drops to zero by three orders of magnitude, for sample 2 (Fig. 1). At larger current densities, the weaker Josephson junctions switch to normal resistivity, resulting in a temperature shift of the drop, as shown in Fig. 3. The plateau in resistivity occurring below the 80% drop (Fig. 1) for the higher current density of 0.5 A/cm², and Fig. 2 curve ⑥) may be ascribed to switching of junctions to the normal state.

The way the samples have been prepared seems to be of crucial importance: Michel et al. [21] obtained a single-phase perovskite by mixing the oxides of La and Cu and BaCO₃ in an appropriate ratio and subsequent annealing at 1,000 °C in air. We also applied this annealing condition to one of our samples, obtained by the decomposition of the corresponding oxalates, and found no superconductivity. Thus, the preparation from the oxalates and annealing below 950 °C are necessary to obtain a non-perovskite-type phase with a limited temperature range of stability exhibiting this new behaviour. The formation of this phase at comparatively low temperatures is favoured by the intimate mixture of the compo-

nents and the high reactivity of the oxalates owing to the evolution of large amounts of H₂O and CO₂ during decomposition.

IV. Conclusion

In the concentration range investigated, compounds of the Ba-La-Cu-O system are metallic at high temperatures, and exhibit a tendency towards localization upon cooling. Samples annealed near 900 °C under reducing conditions show features associated with an onset of granular superconductivity near 30 K. The system consists of three phases, one of them having a metallic perovskite-type layer-like structure. The characterization of the new, apparently superconducting, phase is in progress. An identification of that phase may allow growing of single crystals for studying the Meissner effect, and collecting specific-heat data to prove the presence of high T_c bulk superconductivity.

The authors would like to thank H.E. Weibel for his help in getting familiar with the conductivity measurement system, E. Courtens and H. Thomas for discussions and a critical reading of the manuscript.

Note Added in Proof

Chemical analysis of the bulk composition of our samples revealed a deviation from the ideal La-Ba ratios of 4 and 5.66: The actual ratios are 16 and 18, respectively. This is in agreement with an identification of the third phase as CuO .

DECLARATION OF RICHARD L. GREENE
WITH RESPECT TO HIGH T_c SUPERCONDUCTIVITY

Commissioner of Patents and Trademarks
Washington, D.C. 20231

Sir:

I, Richard L. Greene, hereby declare and say that:

1. I received a Ph.D in physics from Stanford University in 1967, and joined the San Jose, California laboratory of the Research Division of International Business Machines Corp. in 1970. I was the Manager of a group conducting research on organic superconductors and have worked in the field of superconductivity for 20 years. I transferred to IBM Corp. research laboratory in Yorktown, New York, in July 1986, and continued thereafter to conduct research on superconductive materials. From about October 1986 to the present I have worked on high T_c superconducting oxides.

2. At approximately the end of September - first week of October, 1986, my manager, Chang C. Tsuei, showed me a copy of an activity report from the Zurich Research Laboratory of IBM Corporation. This activity report described the work of J.G. Bednorz and K.A. Mueller and their discovery of new superconducting compositions. These materials were mixed copper oxide ceramics that exhibited an onset of superconductivity at a temperature significantly higher than the transition temperatures reported for previously known superconductors. Materials of this general class are now known in the art as high T_c

YO987-074

superconductors. A true copy of this activity report is attached hereto and labeled Exhibit A.

3. Soon after reading this activity report and discussing it with Chang C. Tsuei, I called K.A. Mueller in Zurich and requested samples from him so that I could make measurements on these samples in the United States. This telephone call occurred approximately October 1 - October 6, 1986. My intent was to begin a research project on these materials, as I was very interested in them based on my previous work in superconductivity. My plan at that time was to do experiments which would be complementary to those being conducted by Bednorz and Mueller in Zurich, so that a maximum amount of information could be obtained about these new superconducting materials. Based on the data in this activity report and on the results of susceptibility measurements described to me by Alex Mueller in the aforementioned telephone call, I believed that a new class of superconducting materials with T_c greater than 30K had been discovered.

4. In approximately mid-October, 1986, Praveen Chaudhari, Vice-President, Science, at IBM's Watson Research Laboratory visited the Zurich IBM Lab. Based on my request for samples of the new superconducting material, Chaudhari told me that he had obtained them from Bednorz and Mueller and brought them back to the United States with him. These were about six samples in the Ba-La-Cu-O system. Chaudhari returned to the United States on or about October 20, 1986 and delivered these samples to me. Of these approximately six samples, they varied in the different amounts of La and Ba that were present. Only two of the samples were reported as being single phase materials.

5. Immediately upon receiving these samples, I was in contact with Bednorz and Mueller, via telephone and computer system links, in order to discuss with Bednorz and Mueller the experiments that I would conduct and also to obtain information from Bednorz and Mueller relative to the characteristics of the samples. I had planned to do specific heat measurements of the samples and also resistivity versus temperature measurements in the presence of a magnetic field. Because of the importance that I attributed to this work, I worked substantially full time on these superconductor materials in order to further characterize them. My first specific heat measurements occurred approximately October 29 and 30, 1986, while I measured resistivity versus temperature in the

YO987-074

presence of a magnetic field in late November, 1986. Continuously throughout the period, October 20, 1986 - February, 1987, I worked on a daily basis to further characterize these materials. At all times, I was in contact with Bednorz and Mueller, exchanged data with them, and worked in close cooperation with them. They provided information to me about the characteristics of the material, as well as providing me up-to-date information concerning the data they had obtained about these materials. A true copy of my computer log from October, 1986 - January 12, 1987 is attached hereto and labeled Exhibit B. Excerpts which do not relate to superconductivity have been deleted. In this exhibit, the identifier for K.A. Mueller is "KAM", while the identifier for J. G. Bednorz is "BED". Bednorz and Mueller are located in Zurich, Switzerland and the computer node for them is ZURLVM1. My identifier is "RGREENE". This computer log details my ongoing computer dialogue with Bednorz and Mueller relative to theirs and my activities on the high T_c superconductor materials. In addition to this computer correspondence, I also talked with Bednorz and Mueller via telephone.

6. During my specific heat measurements of these materials, as well as the measurements of resistivity versus temperature in the presence of a magnetic field, I was assisted by Albert M. Torressen, who was a laboratory specialist. I also discussed my laboratory experiments with Chang C. Tsuei, S. von Molnar, Merril W. Shafer, Sung Il Park, Thomas Penney, and Arthur R. Williams.

7. The specific details of the apparatus and the data obtained in the specific heat measurements will be described in a separate statement by Albert M. Torressen, the laboratory specialist who worked with me to provide these measurements. Essentially, the specific heat of the apparatus was calculated to provide calibration and background specific heat, after which the sample was introduced into the apparatus and the total specific heat again measured. By subtracting the background specific heat, the specific heat of the superconducting sample is determined. This was done over a temperature range of approximately 2-50K.

8. The specific heat measurements of these superconducting samples were begun approximately October 21, 1986, and were conducted on a daily basis by me and Al Torressen through November and December, 1986.

These specific heat measurements and the curves which were plotted are representative of these superconducting materials, and are also representative of the specific heat versus temperature plots obtained on present samples of superconducting high T_c oxides.

9. In addition to the specific heat measurements described hereinabove and in the accompanying statement of Albert M. Torressen, I also performed measurements of resistivity versus temperature in the presence of a magnetic field, for the samples of Ba-La-Cu-O obtained from Bednorz and Mueller. The specific heat measurements were performed first on these samples, after which I measured resistivity versus temperature in an applied magnetic field, in order to further characterize these samples. These resistivity measurements were done at the end of November, 1986, and the beginning of December, 1986. Exhibit C is a true copy of nine pages of my data notebook, together with a copy of the cover of this notebook entitled "Zurich oxide BLCO DATA (T,H)." The date "11/15/86" is also on the cover. Exhibit D is comprised of several pages of plots of resistivity versus temperature for these superconductor samples, as well as resistivity as a function of magnetic field at particular temperatures. In some instances, the RuO_2 sample holder is taken into account into the plots. Generally, these plots represent the graphical expressions of the data contained in Exhibit C. Exhibit E is a composite plot incorporating the different plots found in Exhibit C, and shows resistivity versus temperature for different values of applied magnetic field. I used this composite plot at a seminar that I gave to other researchers at the Yorktown lab on December 12, 1986.

10. In order to obtain the data listed in Exhibit C, I used a laboratory belonging to Stephan von Molnar. Albert M. Torressen, who reported to von Molnar, showed me the necessary equipment to make these measurements, and I preceded to make them on my own. However, many people were aware of these resistivity measurements and viewed the data, including both Thomas Penney and Albert Torressen. In addition, Thomas Penney observed me making these measurements and understood the procedure and nature of my laboratory work.

11. I have numbered the data pages of Exhibit C in red in the upper right hand corner. Page 1 describes the sample set-up that I used for these measurements and the background data in order to ready the

apparatus for the resistivity versus temperature measurements. This sample was the BICO -21 II, standing for Ba-La-Cu-Oxide material. Page 2 shows two views of the experimental apparatus and the calibration measurements made between particular terminals. The wires A, B, C and F are those which are also shown on page 1.

12. On pages 3, 4, and 5 I had listed the data that applied to the RuO_2 sample holder and the four point probe. The sample was contacted with indium contacts and copper wires were attached to the indium contacts for the measurements. Both DC and AC measurements were made. The resistance of the sample is R_{FC} which was measured at various temperatures with the applied magnetic field H equal to zero (page 4). Pages 5 - 9 show further measurements that were made at different temperature settings and applied magnetic fields. All of the data on these pages were taken by me and entered by me in this notebook.

13. The plot of resistance versus temperature in exhibit D is a plot for the data which was obtained December 3 - December 5, 1986. Referring to Exhibit D, this plot shows the superconducting transition that begins to occur about 35K, where the transition shifts to the left in the presence of a magnetic field. This is an indication of a superconductor.

14. All acts performed by me as described hereinabove occurred in the United States.

15. I further declare that all statements made hereinabove are of my own knowledge and are true and that all statements made on information and belief are believed by me to be true. Further, I declare that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of a Patent Application or any patent issuing thereon.

Novel Research

Possible High-T_c Superconductivity in the Ba-La-Cu-O System

J.G. Bednorz and K.A. Müller (Project 4196)

We observed a steep decrease of resistivity in sintered Ba-La-Cu-oxide samples, with the highest temperature of the onset in the 35 K range (Fig. 1).

The Ba-La-Cu-O system exhibits a number of oxygen deficient phases with perovskite-like layer-type structures. These are characterized by mixed-valent copper ions (Cu^{2+} and Cu^{3+}) and itinerant electronic states. In addition one expects polaron formation induced by the strong Jahn-Teller effect of Cu^{2+} in an octahedral oxygen environment. Thus our Ba-La-Cu-O system was anticipated to have considerable electron-phonon coupling and metallic conductivity.

Compounds with the composition $\text{Ba}(x)\text{La}(5-x)\text{Cu}(5)\text{O}(5[3-y])$ have been prepared in polycrystalline form. Samples with $x < 0.2$ and $y > 0$, annealed below 900°C under reducing conditions, consist of three phases, one of them a perovskite-like mixed-valent copper compound with K_2NiF_4 type structure. Upon cooling, the samples show a linear decrease in resistivity, then an approximately logarithmic increase, interpreted as a beginning of localization. Finally a steep decrease by up to three orders of magnitude occurs, reminiscent of the onset of percolative superconductivity. The highest onset temperature is observed in the 35 K range. It is markedly reduced by high current densities (Fig. 1). The slow sensitivity decay towards low temperatures might possibly result from 2D superconducting fluctuations of perovskite layers of one of the phases present.

Alex;

Have you made any decision on my proposed specific heat experiment? I am anxious to try it. I think I can do it rather quickly after getting some samples. It may be difficult to see the transition near 30K because of a large phonon background but at the very least we could get a good estimate of the electron density of states and the Debye phonon contribution. Once I have a good specific heat between 2K and 40K I can make a better effort to resolve the electronic effect at T_c if it is small....I think I can see a 1% effect if the transition is not too smeared in temperature. Perhaps you would like to come to Yorktown and work with me on this experiment? Let me know. Best regards.

Rick

P.S. This is a good time for me to do some experiments on your exciting new compound since I am not heavily involved in other projects yet. I could get access to tunneling and neutron scattering equipment which would be very useful for seeing which phonons (if any) are involved in causing such a high T_c .

Date: 14 October 1986, 10:42:19 EDT From: RGREENE at YKTVMZ To: KAM at ZURLVM1

Hi Alex:

This note is to give you my user id and node on the VM system. You can see them above. When you send the samples for the specific heat experiment let me know via VM. My office at Yorktown is 02-026. I will make the specific heat my highest priority and should be able to start the experiment as soon as the samples arrive. I will keep you informed on the progress of the experiment.....it will probably take a few weeks to get reliable data assuming there are no unexpected problems.

As I said on the telephone you can ignore the sample dimensions sent to you by my manager C. Tsuei. He did not talk to me before sending you his VM note and he did not understand the requirements of the specific heat apparatus. What I need are samples to cover an area of 2mm x 2mm on the bolometer. Some extra samples will also be necessary in case we break or lose the primary samples. It would be best to not compress the samples or bind them together with any foreign materials which could alter the specific heat.

Best Regards,

Rick

Rick

Date: 16 October 1986, 09:06:42 EDT From: RGREENE at YKTVMZ To: GGRIN

I'm thinking about taking my son to Mohansic tomorrow afternoon around 1:30. If you want to join us let me know.

Rick

Date: 16 October 1986, 13:27:32 EDT From: RGREENE at YKTVMZ To: JBMART

The reference is PRL 57, 1177(1986). I think a pressure experiment might be interesting. Let me call Chaikin and Brian first then I'll get back to you.

Rick

Greene

Date: 20 October 1986, 08:51:36 EDT From: RGREENE at YKTVMZ To: LOUGHRAN at ALMVMC

Hi Diane;

Starting to get cold around here but at least the sun is shining. Hope all is well with you. You can discard the Chaikin-Greene manuscript. It's been published and I have the reprints. Thanks for forwarding any remaining mail that comes to Almaden.....it takes a long time for scientific types to know when one has moved. I'll be seeing you in Jan.

Regards,

Rick

Date: 20 October 1986, 15:18:13 EDT From: RGREENE at YKTVMZ To: KAM at ZURLVM1

Alex;

The samples have arrived. They are bigger than I expected and all appear to be compressed pellets. Before I start on the specific heat I need to know a few things.

1. What is the difference between the samples marked I(red) and II(black)?
2. Have the samples been compressed with any foreign material, such as a binder?
3. Can the samples be cut without falling apart? If so do you recommend using a string saw or a razor blade or something else? Will water damage them?

4. Has the magnetic susceptibility been measured on any of these samples or on other samples from the same batch? I may want to measure the resistivity or susceptibility on these particular samples to make sure they exhibit the behavior you found before spending a big effort on the specific heat.

We are measuring the background specific heat of our apparatus up to 40K tomorrow...hopefully by the end of the week we will begin your samples so please call or send me via VM the answers to the above questions as soon as possible.

Best regards,
Rick

Rick

Date: 23 October, 1986, 13:43:17 EDT From: RGREENE at YKTVNZ To: BED
at ZURLVM1 cc: KAM at ZURLVM1

Hi George , Alex;

Just a note to keep you informed of our progress. We are almost finished with the background specific heat. Tomorrow we will mount a 25mg slice of your sample BLCO2....it should take about a week to get the data in the earth's magnetic field. It probably will be necessary to also measure the specific heat in a magnetic field to accurately determine the superconducting contribution. Do you have any data on the critical field for this sample...if not we can measure it ourselves. Also I need to know if the samples you sent me are each a single phase....from your x-ray studies. I haven't received your preprint yet....perhaps some of my questions are answered there.

I will be away from the lab tomorrow and look forward to your response on Monday. Best regards.

Rick

Date: 23 October 1986, 14:00:11 EDT From: RGREENE at YKTVNZ To: MALOZEM

Alex;

Sorry I haven't gotten back to you but I have been very busy with two exciting experiments....the specific heat of the new Zurich high

temperature superconductor and the 2D melting X-ray experiment with Paul which finally looks like it will work. I'm not really sure if there are any easily defined X-ray experiments that can be done to prove or disprove the nice model you presented this morning but I will think more about this. However given my present experimental commitments it will be a few months before I could realistically do anything. Keep me informed. Thanks.

Rick

Date: 23 October 1986, 14:27:22 EDT From: RGREENE at YKTVMZ To: BED at ZURLVM1

George; Thanks for the Susceptibility info. I'm glad that I chose BLC02 I for the first experiment. How wide in temperature is the para-diamagnetic transition in this sample? Regards.

Rick

Date: 23 October 1986, 18:58:35 SET From: j.g.bednorz
BED at ZURLVM1 To: RGREENE at YKTVMZ

Hi Rick

Here are the results of our susceptibility measurements, done on the samples You got from me. I'll give You the temperatures where the para- to diamagnetic transition occurs.

BLC02 I 32K	BLC02 II 26-27K
BLC08 I 13-14K	BLC08 II 25-26K
BLC021I 25K	BLC021II 27-28K

So You don't need to involve somebody else with these measurements, which I prefer doing myself here.
While typing this, I got the message that You send a note.

Salu
George.

Date: 28 October 1986, 17:30:52 EST From: RGREENE at YKTVMZ To: BED
at ZURLVM1, KAM at ZURLVM1

Hi George, Alex:

Did you get the last two notes that I sent you? I'm measuring BLC02 this week...nothing definitive yet. I'll keep you informed. What is the critical field of this sample? Is BLC02-I all the same phase? I haven't received your preprint yet...have you sent it? Best regards.

Rick

Date: 29 October 1986, 17:20:53 EST From: RGREENE at YKTVMZ To: GGRIN

Hey Rod;

Date: 29 October 1986, 16:41:22 SET From: j.g.bednorz
BED at ZURLVM1 To: RGREENE at YKTVMZ

Hi Rick,

Sorry for letting you wait so long to get an answer. Alex told me that he sent the reprint already 10 days ago. I have sent you a second one today, in case the letter got lost somewhere.

Concerning your questions:

From our measurements we can tell you that the critical field H_{c2} is higher than 1.5 kG.

Now about the phases present in our samples:

BLC02 I	3 phases:	" ^o cub. perovskite/tetrag.	perovskite/CuO
BLC02 II	2 phases:	"	/
BLC08 I	2 phases:	"	/
BLC08 II	1 phase :	-----/	"
BLC021I	2 phases:	"	"
BLC021II	1 phase :	-----/	"

Best regards also from Alex

George.

Date: 30 October 1986, 09:20:04 EST From: RGREENE at YKTVMZ To: GRANT
at ALMVMC

Hi Grantie;

I'm here ..where are you? Don't even have a phone answer any more. How come you didn't answer the questions in my last note.

As for the 3M meeting I am supposed to share a room with Torrance starting Sunday nite. I'm not sure if he's still coming or how long he's staying. Check with him and you can share the room with us or replace him. Let me know.

Greene

Date: 30 October 1986, 09:31:20 EST From: RGREENE at YKTVMZ To: BED
at ZURLVM1, KAM at ZURLVM1

Hi Alex and George:

I just tried to reach you by telephone without success so here is a note. We have measured the specific heat(C) of BLC02-I from 2-40K...the analysis is not yet complete but the preliminary data does not show any bump in C near or below 32K. However at this stage we could only see a bump or jump if it was greater than 10% of C so more accurate ex-

periments will be required. Since BLC02-I is a 3 phase sample it was not a good choice for the measurement since I will not be able to analyze the data for density of states and Debye Temp. Do you know how much of each phase is present in this sample? Also is the cubic perovskite a metal or insulator?

It would be better if you had some single phase single crystals of the tetragonal phase. Is this possible? We could measure samples as small as a few milligrams.

Without crystals I am planning to measure BLC08-II next since this is a single phase. Once you send me the info on the chemical composition and structure of this phase I can analyze the data and hopefully get results that we can publish. The measurements will take another week if all goes well. If we have to put on a magnetic field this will take several more weeks... specific heat data is tedious to obtain and analyze even with a computer.

Please answer the above questions as soon as possible. I am still waiting for your preprint... the first one must have gotten lost. Did you send it by external mail? Best regards.

Rick

Date: 30 October 1986, 18:30:43 SET From: j.g.bednorz
BED at ZURLVM1 To: RGREENE at YKTMZ

Hi Rick,

BLC02III or BLC08II would be good to try.

BLC02III shows a more pronounced resistivity drop, as compared to the sample I. BLC08II I could not check till now.

The composition is $\text{Ba}_{0.15}\text{La}_{1.85}\text{CuO}_{4-x}$ and $\text{Ba}_{0.10}\text{La}_{1.90}\text{CuO}_{4-x}$ respectively. The structure of La_2CuO_4 is a layered perovskite of K_2NiF_4 type.

The pure material is orthorhombically distorted. Exchanging La by Ba is leading, as we believe, to the formation of a tetragonal unit cell.

Our powder diffraction pattern can be indexed with a bodycentered lattice and $a=3.79\text{\AA}$ and $c=13.21\text{\AA}$ for $x\text{Ba}$ around 0.1. For crystals with $x\text{Ba}=0.02$ I also checked the lattice parameters by single crystal

precession experiments. But here we already have the problem. These crystals have been obtained from powders with $x\text{Ba}=0.1$, so we have to expect segregation and it will take a while, to get the crystals with a composition where the resistivity drop is observed in the powders.

To your question about the cubic perovskite, it shows metallic conductivity as well.

I really hope, that you get the preprint very soon.

Best regards George.

Date: 30 October 1986, 15:06:11 EST From: RGREENE at YKTVMZ To: BED
at ZURLVM1

George; Thanks for your quick answer to my questions. I forgot to ask you if you know the relative weight % of the 3 phases in sample BLC02-I. If so I may still be able to get some useful information from the data we have taken so far.

I also just realized that you could send me the preprint via VM assuming it was typed on line. Please see if your secretary can do this. Thanks and regards.

Rick

Date: 3 November 1986, 16:58:28 EST From: RGREENE at YKTVMZ To: JERRY
at ALMVMC

Hi Jerry;

All is set for our room at the Hyatt starting Sunday nite the 16th. I'm not sure when I'll arrive but they have your name attached to the room also and it's guaranteed for late arrival. See you there. I saw some article recently about an organic ferromagnet....I think in JETP letters. Do you know about that work?

Rick

Date: 4 November 1986, 17:00:53 EST From: RGREENE at YKTVMZ To: SANDRO

I cannot play tomorrow...sorry. Next week. If I can change my schedule tomorrow I will call you in the morning.

Rick

at ZURLVM1

Hi George;

No I have not given up...in fact I just tried to reach you by phone. My terminal is not working since I just changed my office so it may take me a little longer to respond to messages.

At any rate I have finished the specific heat measurement from 4-35K in zero magnetic field. It will take a few days to finish the data analysis but there is no obvious bump in the specific heat indicating superconductivity. This is not really too surprising given the very broad transition you have found in resistivity and susceptibility.

I expect to get some useful information from the data anyway but for this I need the exact composition of BLC021-II. Is it Ba_{1.5}La_{1.85}CuO(4-.15)? Please send this as soon as possible by VNET....I will get back to you and Alex later with more info. Regards.

Rick

Alex;

I'll be happy to talk about the prospects of using magnetic X-ray scattering for thin films and interfaces. It will only be a summary of what has been done and my thoughts on what else could be done. The rest of your proposed program looks great. It's a good idea to have such an internal meeting.

Rick

Date: 14 November 1986, 10:17:09 EST From: RGREENE at YKTVMZ To: BED
at ZURLVM1, KAM at ZURLVM1

Hi Alex and George;

I will be away from the lab until 24 Nov. so I thought I would let you know the present status of the specific heat (SH) experiment and my future plans.

So far we have measured BLC021 from 3-35K. There is no evidence for a bump in SH anywhere....to a 5% accuracy. I have analyzed in detail the data between 3-10K. Here the SH is linear on a C/T vs T² plot. The intercept gives a value for gamma of 5.9 mj/mole-K². This is a rather large value compared to other metals and suggests that most of the BLC021 sample is in the normal state. However to be sure of this we must measure the sample in a magnetic field large enough to suppress the superconductivity. This we will start while I am away. Also we must run a test sample such as copper or silicon to know the accuracy of our gamma determination. All this will take 2-3 more weeks. As you see it takes considerable effort to do a reliable specific heat measurement which makes it very important that we have well characterized, single phase samples. As we discussed yesterday George it may be better to do the SH experiment on a bunch of single crystals if you can prepare them. Five mg of material should be enough to get reliable data.

We will also measure the critical field up to 9T via resistivity. I want to do this first so I have some idea of the field necessary to get the normal state at 3K....our SH apparatus has a field of 5T maximum.

I'll talk with you when I return. I am still quite excited about these new materials and hope that we can continue to collaborate on various experiments even if the specific heat does not give evidence for bulk superconductivity. I should remind you that it took many years of work before the BaPbBi Oxides were shown to be bulk Superconductors.

Best regards,
Rick

Date: 25 November 1986, 09:43:48 EST From: RGREENE at YKTMVZ To: PARKIN at ALMVMC

Hi Stuart;

Thanks for your note. I haven't heard from Helmut but he is probably very busy starting his new job. Haven't heard about the Japan proceedings either.....are you still interested in organic metals? What is happening with your work on thin films? I expect to be out to San Jose sometime in January and you can bring me up to date.

Until then I am very busy with X-ray scattering and some other experiments on new inorganic materials. Have a good holiday season.

Best regards

Rick

Date: 25 November 1986, 10:35:50 EST From: RGREENE at YKTMVZ To: BED at ZURLVM1, KAM at ZURLVM1

Hi Alex and George;

I have returned from my trip and will once again start work on your new superconductor. This week is the Thanksgiving holiday so not much will happen until next week. The specific heat apparatus is now modified to make measurements in a magnetic field....however we must first calibrate and check that it works with some known material.

Please tell me what is happening with your studies of time dependent effects. Is the sample BLC021 still good....we have not yet measured the resistivity in a field as a function of T but we plan to along with the specific heat experiment. Perhaps you should send me some new single crystals for the next experiment.....I don't want to waste time on a bad sample.

I would like to send an abstract to the March APS meeting on the specific heat results. Is this agreeable with you? The abstracts are due the end of next week (Dec.5) so let me know soon. At this stage there is not much definitive to say but I can still write a general abstract about specific heat and I'm sure I will have definitive results by the time of the meeting.

Best Regards,
Rick

Date: 26 November 1986, 09:56:43 EST From: RGREENE at YKTMVZ To: KAM
at ZURLVM1

Hi Alex;

Are you sending your susceptibility preprint to people outside of IBM? If so Ted Geballe at Stanford would like a copy...he saw your paper in Z.Physic and called me to see if I knew about your work.

I can send him a copy if you are agreeable. Please let me know about this and more importantly the answer to my note of yesterday.

Best regards,

DU115

Date: 1 December 1986, 17:31:01 EST From: RGREENE at YKTMVZ To: KAM
at ZURLVM1, BED at ZURLVM1

Hi Alex and George:

Here is a draft of the abstract that I would propose submitting to the APS March meeting. Please make any changes or comments and let me know today. I look at this as a way to publize your work in the USA and to present whatever specific heat results are obtained by March.

POSSIBLE HIGH T_c SUPERCONDUCTIVITY IN THE Ba-La-Cu-O SYSTEM

We report measurements on new oxide superconductors of the composition $\text{La}(2-x)\text{Ba}(x)\text{CuO}(4-y)$ with $x \ll 1$ and $y > 0$. Polycrystalline samples with $x = .15$ show a resistivity drop of three orders of magnitude and a transition from Pauli paramagnetism to diamagnetism with an onset temperature between 30-35K. (ref 1 and 2....your two papers). The transition is complete by 10K and magnetic field studies suggest superconductivity of a percolative or granular nature. Our specific heat experiments indicate a large electron density of states but no evidence of a sharp jump near T_c ---consistent with the small Meissner signal observed (2% of complete flux expulsion) and the broad transition width. These measurements, along with X-ray and critical field results, will be analyzed for the possibility of high T_c superconductivity in these new oxide materials.

The authors would be the three of us and Steve VonMolnar (whose apparatus I am using)....possibly I would add Al Torresen (Steve's assistant) without whom the specific heat experiments could not have been done.

The abstract could perhaps be a bit longer but there may not be much space after the authors and references are included.

Regards,
Rick

Date: 2 December 1986, 09:17:12 EST From: RGREENE at YKTVNZ To: KAM
at ZURLVM1

Alex;

I scheduled your seminar for 8 Jan at 3:30pm....this was the only time I could get a room. Please send me a title and short abstract so I can get it on the lab calender as soon as possible. Do you need a hotel reservation? Regards.

Rick

P.S. Plan on saving some time on 9 Jan. to discuss our specific heat data. If you would like to go out together for dinner on the 8th
let me know.

Date: 4 December 1986, 10:48:02 EST From: RGREENE at YKTVNZ To: BED
at ZURLVM1

Hi George;

I just tried to telephone you. I am measuring the resistance and critical field of sample BLC0-21. So far it reproduces the data in your Z. Physik paper...I don't see a bump except perhaps near 25K (but I need to take more points). The surprising thing is that a small field (1000 Oe) increases the Resistance to the value at 25K but at higher fields (up to 7Tesla) there is almost no more change in R. Tell you more when I have more data.....so far it suggests that doing the specific heat in low field will be useful.

Would you please send me whatever info you have on the structure of the superconducting phase i.e. a picture and a powder X-ray that gives the Bragg peak positions.

What have you learned about the time changes in these samples? I would like some fresh single phase samples for our next specific heat experiment...to begin at the end of next week. If you have single crystals that would even be better.....but I realize this is a difficult problem.

regards,

Rick

Date: 5 December 1986, 10:56:34 EST From: RGREENE at YKTVMZ To: ORR

OK. What are you up to? Dropin and see me sometime in vonMolnars lab.

Rick

Date: 5 December 1986, 11:10:42 EST From: RGREENE at YKTVMZ To: KAM
at ZURLVM1, BED at ZURLVM1

Hi Alex and George:

I'm getting some good critical field results now although I still don't totally trust my contacts. The resistance vs. temp. follows your data but there seems to be two superconducting regions (perhaps 2 phases).. one below 22K and the other below 33K. The critical fields are very different in these two temperature ranges. The good news is that I am getting a critical field vs temp curve between 20-30K and this will allow me to estimate gamma to compare with the specific heat gamma. Incidentally the critical field at 4K is greater than 7Tesla (as expected for a high Tc material) so we may eventually want to go to the MIT magnet lab to measure it better.

The specific heat exp. is progressing nicely and we will be finished with all our calibrations next week. What sample do you recommend that I use based on your recent work?

As soon as I have collected and plotted all the critical field data I will send you a figure along with the abstract to the March meeting.

Best regards,
Rick

P.S. Please send me whatever info you have on the structure of the SC phases.

I am giving an internal journal club seminar on your resistivity and susceptibility papers.

at YKTVMZ

Rick, here is the title and abstract for my seminar :

'Superconducting and Structural Properties of the BaLaCuO System'

Resistivity and susceptibility measurements as well as x-ray powder analysis carried out at the Rueschlikon laboratory will be described. The electric and magnetic data indicate the existence of a percolative superconductor with onset above 30 K. The newest magnetisation measurements as a function of temperature and field prove the presence of a superconductive glass. The highest Tc samples correlate with an orthorhombic-tetragonal structural phase transition.

please check for the english, thanks

Alex

Rick

Date: 9 December 1986, 10:37:27 EST From: RGREENE at YKTVMZ To: BED
at ZURLVM1, KAM at ZURLVM1

Hi George , Alex;

Thanks for your note George. I will send you the Critical field data today. It seems to reproduce your low field results and has the data up to 7Tesla....I could go to 9T but will do that later. I assume from your note that you think that BLC021 is still a single phase...is that correct? I will use this sample for the specific heat in a magnetic field.

I am a little puzzled by the critical field data...it suggests that your susceptibility data was measuring the superconductivity that occurs below 20K and the superconductivity above 20K may not be a bulk effect. It's also a little disturbing that I measured such a large linear term in the specific heat in earth field.....the measurements at 5T should clarify this however.

Can you tell me the density of the SC phase? I need this to estimate gamma from the critical field slope. Also what is your estimate of the value of the resistivity just above T_c ? I assume a single crystal would be at least 10 times lower. Also I would like to know your estimate of the Pauli susceptibility above T_c from your data....this will give another estimate of gamma.

Thanks for sending me your info and figures of the structure..I hope it arrives before next Tuesday.

Best regards,

Rick

Date: 9 December 1986, 11:32:57 EST From: RGREENE at YKTVMZ To: MALOZEM

I don't know Creuzet that well but he seems to have done some good work and seems to know what he's talking about. I'm not sure how independent, creative or hardworking he is. What would he be doing here? How closely working with an RSM? Who with?

Rick

Date: 9 December 1986, 14:34:51 EST From: RGREENE at YKTMVZ To: POMERAN

BED at ZURLVM1 To: RGREENE at YKTMVZ

Hi Rick Sorry that you had to wait for the answer since Thursday. I've been in Germany since Friday. In November I told you on the phone, that something happened to that sample BLC021II which I measured again one month after the first resistivity run. The resistivity curve showed a peak at 34K and a shoulder occurring around 25K after a 60 percent drop. At that time I was also surprised about the magnetic field dependence in the low temperature part. The resistance was increased by fields between 0-0.4 Tesla but seemed to saturate at values above, whereas the field dependence of the peak at 34K was smaller. It would be good to compare our results, especially as you have the possibility to go to higher fields than 0.7 Tesla, which is the limit for our resistivity system. Unfortunately I do not see the occurrence of a new phase related to the appearance of that shoulder in the resistivity.

Concerning your internal seminar, I will send you an X-ray powder spectrum and the structure of La₂CuO₄, which I've drawn already, using the information given in a German article. You can even have the viewgraphs. We should discuss questions about the structure at the phone.

Best regards
George.

Date: 9 December 1986, 18:47:08 SET From: j.g.bednorz
BED at ZURLVM1 To: RGREENE at YKTMVZ

Hi Rick,

Thank you for your quick answer. I just discussed with our Japanese guest Masaaki Takashige, who is involved in the susceptibility measurements. First of all you should not be worried about the susceptibility data shown in the preprint, because the samples shown there are not single phases. You will see from the X-ray pattern that the amount of the foreign phase can be very large, greater than in BLC021 I. Single phase means, that in the X-ray diagrams we only can detect the La₂CuO₄:Ba. The small susceptibility could indicate that only parts of that phase is superconducting, for instance an intragranular network. That is the reason, why we think the density of La₂CuO₄ (from the X-ray data = 7 g/ccm) would not lead to a correct estimation in your case. The Pauli susceptibility

of sample BLC021II, this sample is not shown in the paper, shows a field dependence close to T_c , this dependence is getting weaker with increasing temperature, and we expect it to vanish 10 or 20 degrees higher, but in case of this sample it has not been confirmed. I'll give you values at 32-33K for the mass susceptibility:

0.3 Kgauss 1.28 E-7 ccm/g

5.0 " 1.35 E-6 ccm/g

10.0 " 1.61 E-6 ccm/g Especially for the low field value we have to be aware of a large error.

For the resistivity value: My measurement (second one, where I realized the magnetic field dependence) showed a peak value of 7.36 E-3 Ohm cm .

Concerning the results of the Japanese group: Do you know more about it? How did they measure the 40% Meissner effect, did they measure ac or dc? Is something known about the magnetic field they applied? I think they believe the metallic perovskite phase is responsible for the superconductivity, whereas we found that the single phase samples containing $\text{La}_2\text{CuO}_{4.8\text{a}}$ in the powder diffraction pattern, show the highest susceptibilities. You will get the copies of the results as soon as they are plotted.

Best regards

George. can be very large, larger than in BLC021. Talking about single phase samples

les,

Date: 10 December 1986, 10:48:47 EST From: RGREENE at YKTMZ To: GRANT at ALMVMC

I haven't forgotten you....just busy as hell with this 30K superconductor and can't think about anything else. Happy Holidays Turkey.

Looks like I won't have time to ski...too much physics to do.

DC 2 probe

$$AB = 100\Omega$$

$$AF = 88\Omega$$

$$AC = 88\Omega$$

$$BF = 72\Omega$$

$$BC = 73\Omega$$

$$FC = 62\Omega$$

Do AC 4 probe (22 Hz)

$$I = 10\mu A \text{ thru } AB$$

get $12\mu V$ 90° out of phase

$$\Rightarrow 1.2\Omega$$

I thru FC get $12\mu V$ on AB 90° out of phase

I thru FB get $12\mu V$ on AC " " "

I thru FA get $12\mu V$ on BC in phase

go to 50Hz and get in phase signal
with $\sim 80m\Omega$ resistance

Doesn't look good but let's try it anyway
and use LR-400 bridge

DO NOT THROW AWAY

FC = 62

GC = 73

GF = 72

HC = ~~88~~ 85

AF = ~~88~~ 85

AB = ~~100~~ 100

DC

12 # of 79
Sample

At Room T - 4 probe

$$R_{FC} = 75.6 \text{ m}\Omega$$

$$R_{AB} = 44.4 \text{ m}\Omega$$

$$R_{BF} = 7.4 \text{ m}\Omega \rightarrow \text{changes with excitation voltage} \\ + \Omega \text{ scale}$$

Cool down sample anyway using LR-400 / to measure

$1177_5 \pm 0.5$	469 ± 12	$\sim 12.5K$	0.14	is stable

Put on it field now

He boiling off rather rapidly — because sub at 16K
and gas in SVC

try this tomorrow with gas pumped out of SVC

Put sub back at 15K, He³ p ≈ 0

14/86

Run some more T's and H's

I = 300ua

Try increasing current at various T 's

but must worry about heating due to 200 Ω contacts

G	T	$R (m\Omega)$	I (from LR-400 setting)
526	10 K	1.65	300 μA
	"	1.6	30 μA
	"	1.9	1000 μA
	"	2.7	3 mA
		6 mA	10 mA

T increasing

→ but R & T increasing

All this looks like increasing sample T via heating at contacts

Do this when we have better contacts

Estimate of Current Density

Cross section $2.5 \times 2.5 \text{ mm}^2$

$I = 300 \mu A$

$$J = \frac{300 \times 10^{-6}}{.06} \approx \frac{1}{2} \times 10^{-2} \text{ A/cm}^2$$
